

VegDrop

Delivery infrastructure for Andhra Pradesh's Rythu Bazaars

Any market registers itself. Any vendor sells from their own stall.
Any household orders in Telugu, Hindi or English.

Presented to the Hon'ble Sri Nara Lokesh

Minister for IT, Electronics, Communications & HRD, Government of Andhra Pradesh

[phone] · [email]

A vendor's reach ends at their own footpath

1

Reach ends at the stall

A vendor sells to whoever physically walks past, in the few hours the market is open. Their customer base is a stretch of pavement.

2

Unsold produce is a same-day loss

Vegetables are not inventory, they are a clock. What does not sell by closing is written off, by the person who can least afford it.

3

National delivery apps do not come here

They list warehouses and modern retail. A market stall has no warehouse and no fixed SKU list, so it is on no app a household already has.

None of this is a problem the vendor can solve with a better phone. It is a missing layer.

The state already built three of the four layers

01

The markets

Rythu Bazaars have run since 1999 as state-backed farmer-to-consumer markets under market committees. The trust and the network already exist.

IN PLACE

02

Digital marketplace

e-Rythu, built with Mastercard, digitised agri marketplace listings, payments and workflows for farmers and FPOs across the state.

IN PLACE

03

Farmer touchpoints

Rythu Bharosa Kendras and e-Farmarket already connect growers to traders at the village level.

IN PLACE

04

Household last mile

No app a family orders a kilo of tomatoes from, and no rider who carries it from the stall to the door. This is the gap.

MISSING

VegDrop is layer four, and only layer four. It does not replace the bazaar or compete with it — it extends one stall's catchment from a footpath to a whole town.

The seller is a market stall, not a warehouse

Four kinds of people use it, each with their own app, all on one codebase and one database.

The household

Browses the market's produce, builds a basket, pays by wallet or Razorpay, follows the rider. In Telugu, Hindi or English.

Customer app

The stall vendor

Lists what they have today, sets the morning price, confirms yesterday's prices in one tap, packs what the order assigns them.

Shopkeeper app

The rider

Takes a job, collects from each stall against that stall's own code, delivers against the household's code, is paid per order.

Delivery app

Market committee

Registers the market, approves or refuses each stall, sees the market's analytics, and sets how every rupee is divided.

Market owner app

6

separate role apps

3

languages in the UI

1

codebase, one database

0

passwords in the system

Any Rythu Bazaar can register itself

1

The owner walks the perimeter

Standing at each corner, they drop a GPS node. The nodes close into a boundary on the map.

2

A vendor applies from inside it

The application is accepted only if the phone's location sits inside that boundary, recently enough.

3

The committee approves

Each application reaches the owner with the applicant's name, number, stall number and location check.

4

The vendor proves the bank account

A randomised penny drop of 1 to 100 paise, reported back exactly, before they can list one item.

Why this matters more than any feature in the app

No state official does data entry. No central team visits a market. No engineer is needed to add one.

The hundredth Rythu Bazaar joins exactly the way the first one does — the committee walks its own perimeter on a phone. That is why this can be a people's platform rather than a pilot: the onboarding cost per market is one walk, borne by the market itself.

One basket, several stalls, two handovers

1

Basket placed

A household orders five items from one market.

2

Split by coverage

The fewest stalls that cover the basket, so a rider walks to two pitches, not five.

3

Stalls pack

Each stall sees only its own lines. The order moves on when every line is ready.

4

Rider collects

At each pitch the rider types that stall's own six-digit code.

5

Household confirms

At the door the rider types the code the household is shown. Only then is it delivered.

The rider types both codes and is shown neither

No screen or endpoint will put either code in front of a rider's session. A false handover needs two people to agree to it.

A code exists only once someone has been shown it

It is created the first time its holder opens it, so a code nobody has seen cannot be redeemed, and five wrong guesses kill it.

Built so this cannot come back on you

A No passwords exist

Possession of the phone number is the only credential. No password field, no reset, nothing to leak or reuse. Codes arrive over WhatsApp.

B A bank account is proven, not typed

A randomised 1-100 paise deposit, reported back exactly. The account number is encrypted at rest and only ever shown as the last four digits.

C Money is integer paise, never a float

Every amount is whole paise. A wallet balance is derived from an append-only ledger, not a field anyone can edit, and crediting is idempotent.

D Nobody sees another's business

Order visibility is scoped by role on the server, on every request. One vendor cannot read another's customers, prices or volumes.

E A suspension takes effect at once

Role and verification status are re-read from the database on every single request, so a de-verified vendor stops trading immediately.

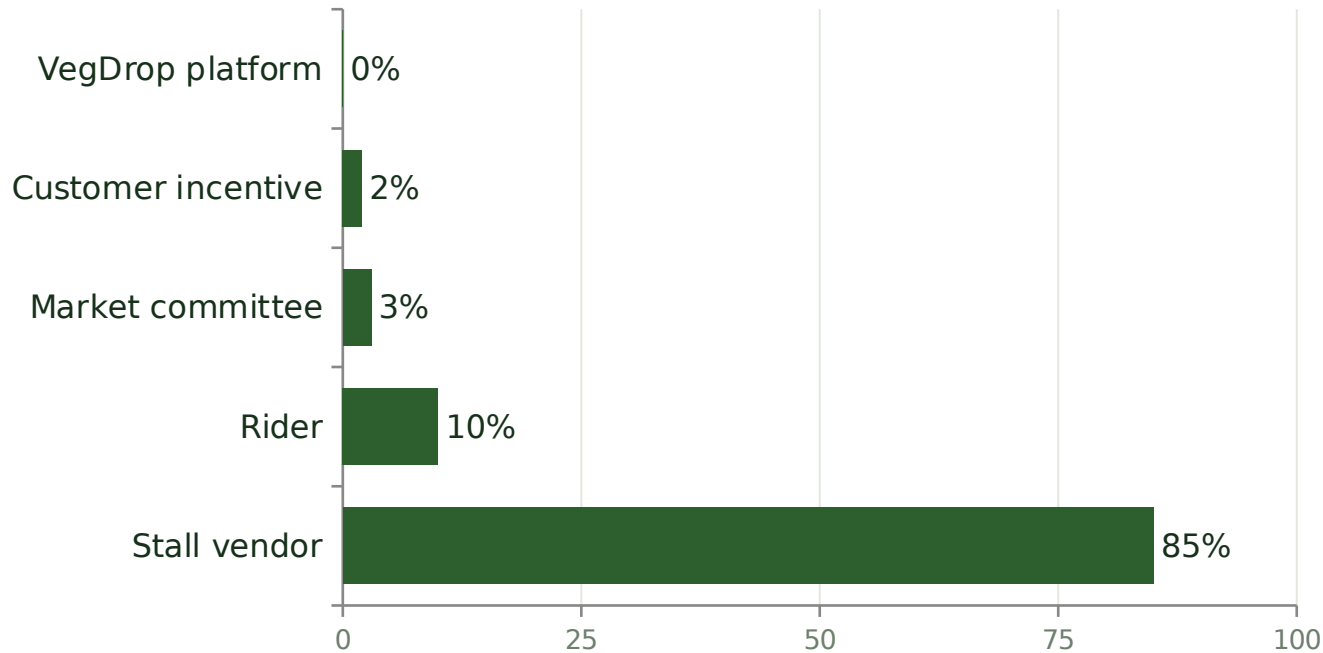

F 67 automated test suites on the server

Covering settlement arithmetic, authorisation boundaries, handover-code leakage, geo-fencing and migrations. They run on every change.

Every item above is in the code today and can be read by any auditor your department nominates.

The market sets the split, not the platform

Every order's gross is divided into five buckets that must add up to exactly 100%. There is a state-wide default and a per-market override, so a Rythu Bazaar can run on different terms from a private market.

Illustrative split, not a fixed rate. The committee chooses these five numbers.

Commission has exactly one source of truth in the ledger. It is never re-derived as a percentage of sales, so no screen can report revenue the platform never took.

0%

is the platform commission the software ships with. Not a launch offer — the shipped default.

What that means for a Rythu Bazaar

The state or the committee can set the platform's cut to nil, and VegDrop takes nothing from the vendor.

The rider's and committee's shares are then the only deductions, visible to the vendor line by line.

What one market at steady state would mean

Assumption: one market of 60 stalls serving 300 households a day at an average basket of ₹250. Nothing here is measured yet — the arithmetic is shown so you can reject the assumption rather than the conclusion.

₹75,000

**of produce moved
per market per day**

300 baskets × ₹250.
Demand that no longer
depends on who walks
past the stall.

₹22.5 L

**per market
per month**

The same arithmetic over
30 market days, flowing to
vendors rather than an
intermediary.

~10

**rider earning slots
per market**

At roughly 30 deliveries
per rider per day, paid per
order from the same
ledger.

~1,000

**rider slots if
100 markets register**

Onboarding costs one
perimeter walk per
market, so this scales
without state headcount.

The job this creates is a rider's, and it is created in the vendor's own town.

Not a software job in a metro — a delivery shift that pays per order, in the district the market is in, with the earnings on a ledger the rider can read. I am not asking you to take these numbers on trust. The last slide is what I will come back with, measured.

Where the project actually stands today

Built and working

- All six role apps end to end — order, split, pack, collect, deliver, settle
- About 93,600 lines of code, 27 data models, 20 API modules
- 67 automated server test suites, run on every change
- Telugu, Hindi and English through the customer interface
- Razorpay payments and RazorpayX vendor payouts integrated
- GPS market boundaries, penny-drop verification, handover codes
- A cooking assistant with 83 hand-checked recipes that fills a basket

Not yet true

- **Zero real orders. Not one. No household has used this.**
- Not in production — it runs as a working demonstration
- No market has registered and no vendor has been verified
- Needs a WhatsApp authentication template approved for real sign-ins
- No external security or financial audit has been done
- Rider supply, basket size and delivery time are modelled, not observed

I would rather you hear the right-hand column from me now than have your office find it later. That column is exactly what I am asking for help to change.

Three things, and only the first one is urgent

1

One anchor Rythu Bazaar, for 90 days

An introduction to one market committee willing to let 20-30 stalls register and trade on the platform for a season.

Cost to the state: one introduction. No money, no staff, no infrastructure.

2

Open the gate once it is proven

If the 90 days hit the targets on the next slide, allow any Rythu Bazaar in Andhra Pradesh to register itself.

The software already works this way. It needs permission, not engineering.

3

A place at the Ratan Tata Innovation Hub

Incubation and acceleration, which already covers cross-sector ventures including food.

Useful, not blocking. Asks one and two matter more.

What I am not asking for: no grant, no subsidy, no government money, no exclusivity, and no commitment beyond the 90 days. If the numbers do not appear, the gate stays shut and the state has spent nothing.

What I will come back with, measured

Five numbers. Each one either appears or it does not, and the ledger behind each is open to your department.

01 25+ stalls registered and bank-verified

In one market, each having proved control of its own settlement account.

02 1,000 delivered orders

Every one with both handover codes recorded against named accounts.

03 Vendor income, before versus during

Per stall against its own baseline — the number that decides whether this is worth scaling.

04 Actual rider earnings per shift

Not a projection. What riders were paid, from the settlement ledger, per shift worked.

05 A ledger auditable line by line

Every rupee of every order traced to its five buckets, open to the committee throughout.

If these five numbers do not appear, the gate stays shut — and that is the correct outcome.
